Agenda

- B+-Trees
 - Introduction
 - Searching, Insertion, Deletion
 - Complexity Analysis
- B+-Tree Advantages

B+-Trees - Introduction

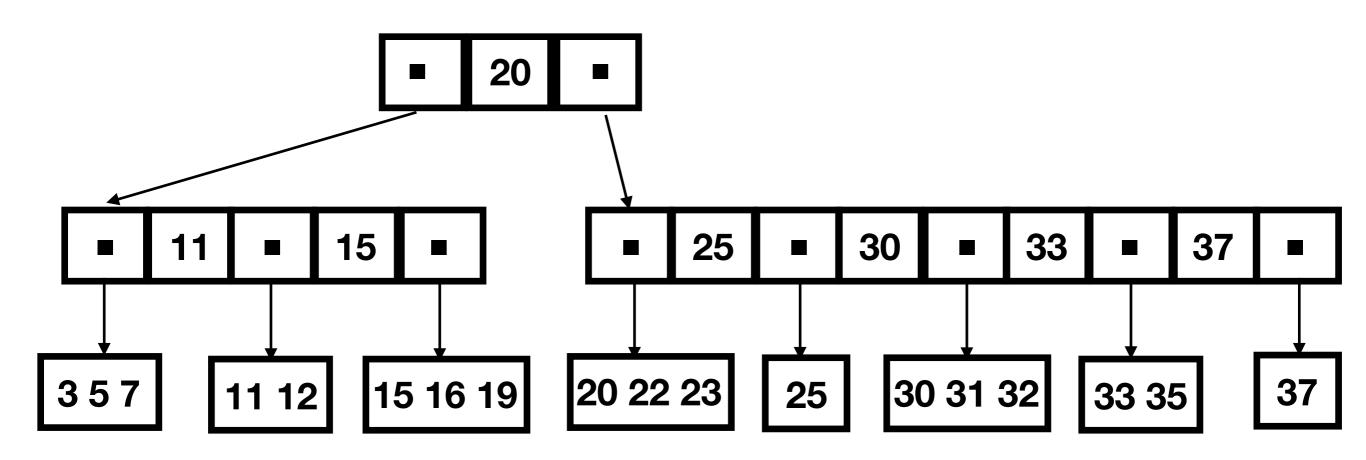

- Disk Storage Problem
 - How to store data on disk for faster access?
 - How about Binary Search trees?
 - # of reads needed?
 - # of root -> leaf traversals?
 - Locality of reference?

- B-Trees and its variants comes to rescue
- B-Tree is a variant of search tree with many children

B+-Trees - Properties

- Key Ideas
 - Reduce # of reads: store more data in each node
 - Reduce # of traversals: high branching factor (B >> 2)
 - Locality of reference: sorted keys

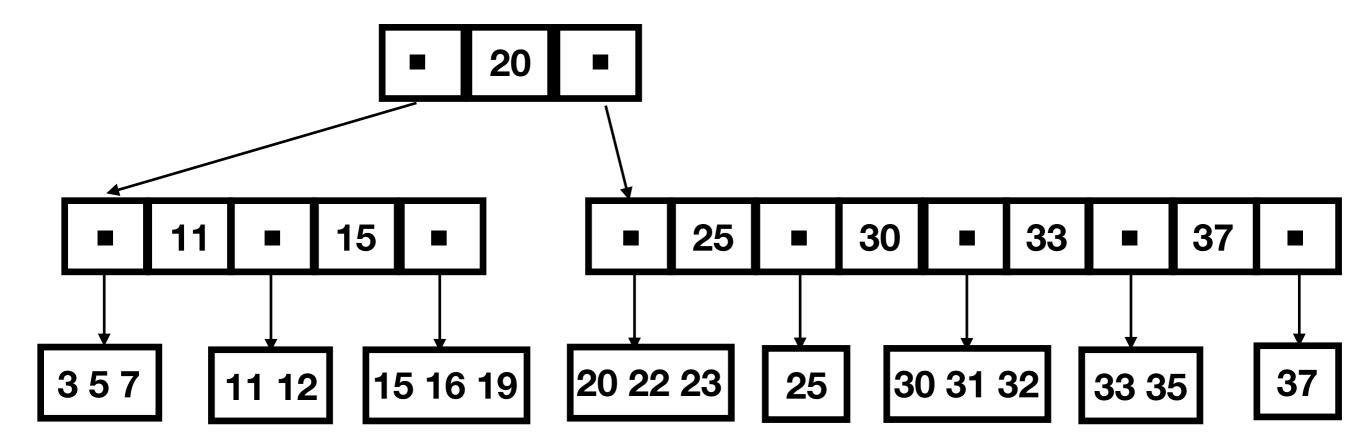

B+-Trees - Example

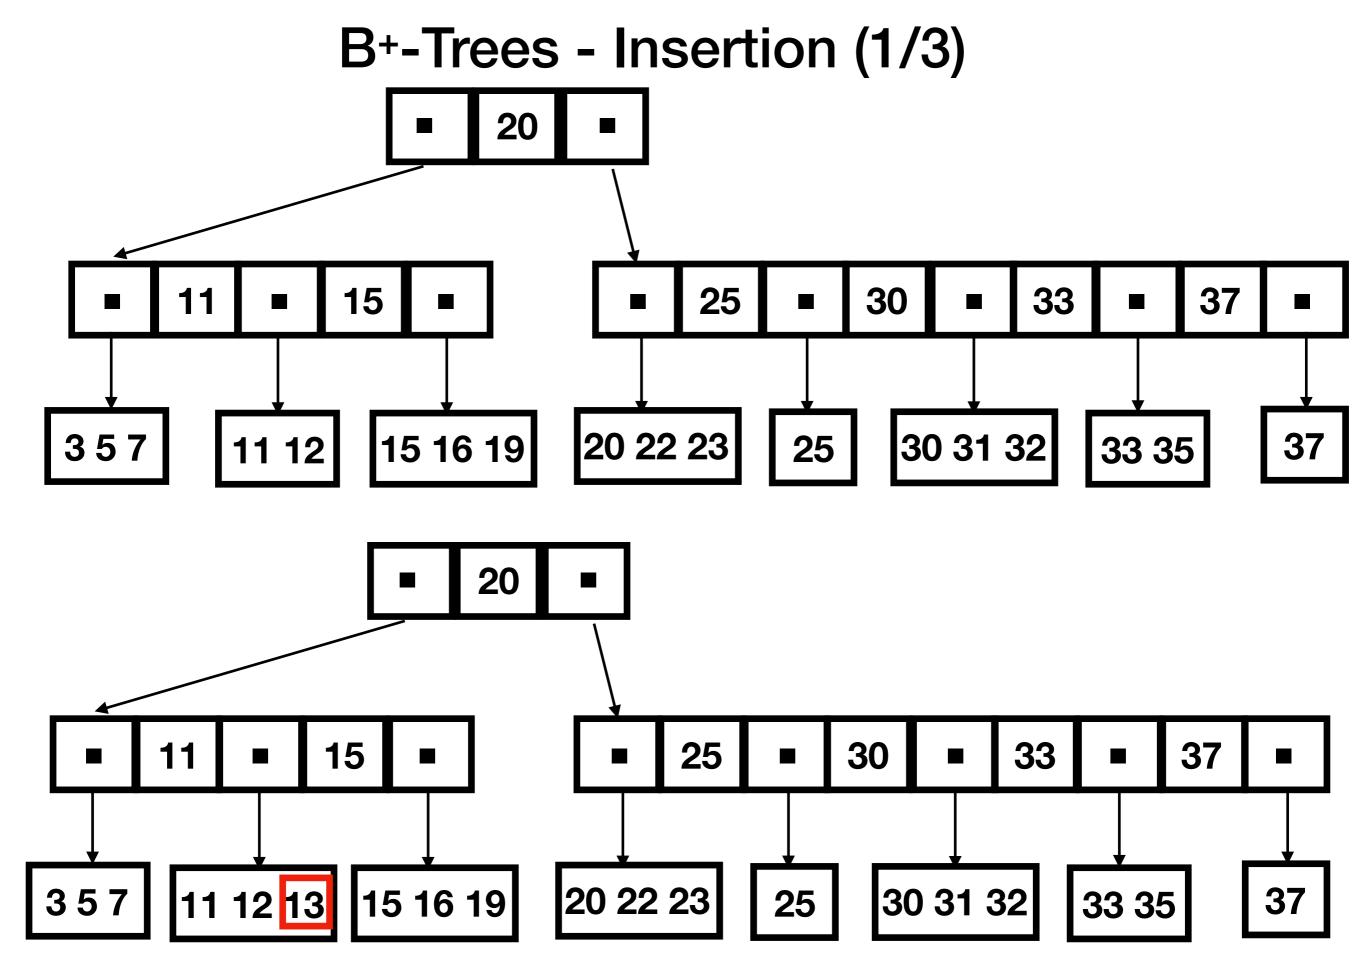

B+-Trees - Formal Definition

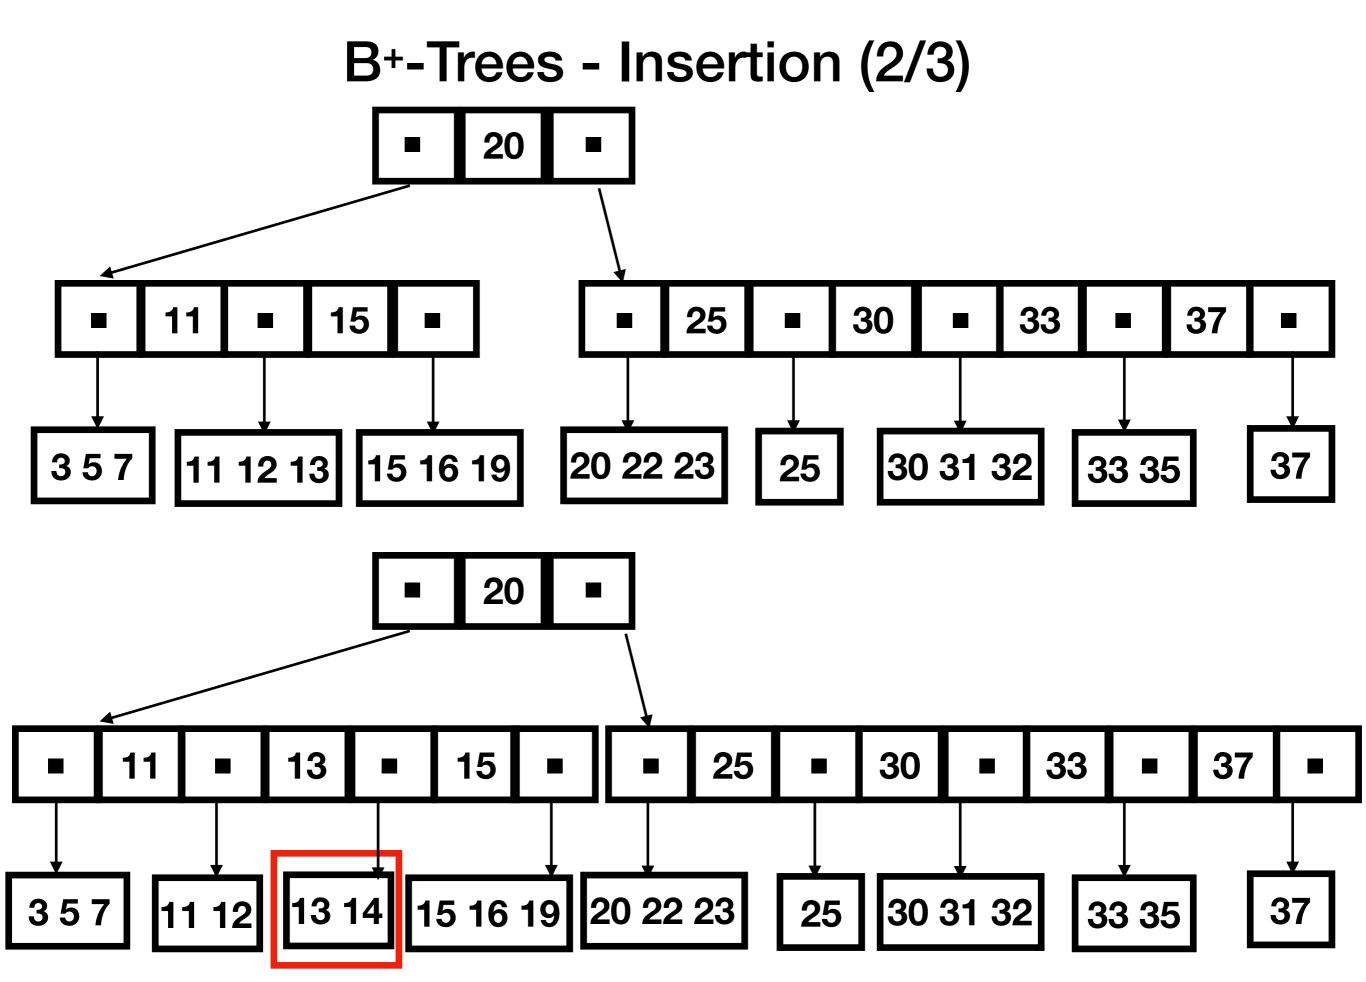

- For non-leaf node N:
 - (# of children in K) (# of keys stored in K) == 1
- For every non-root node N:
 - at least (B-1) keys
- All nodes have at most 2*B children
- All leaf nodes have same depth
- Only leaf node(s) contain data, non-leaf contain routing values

B+-Trees - Search

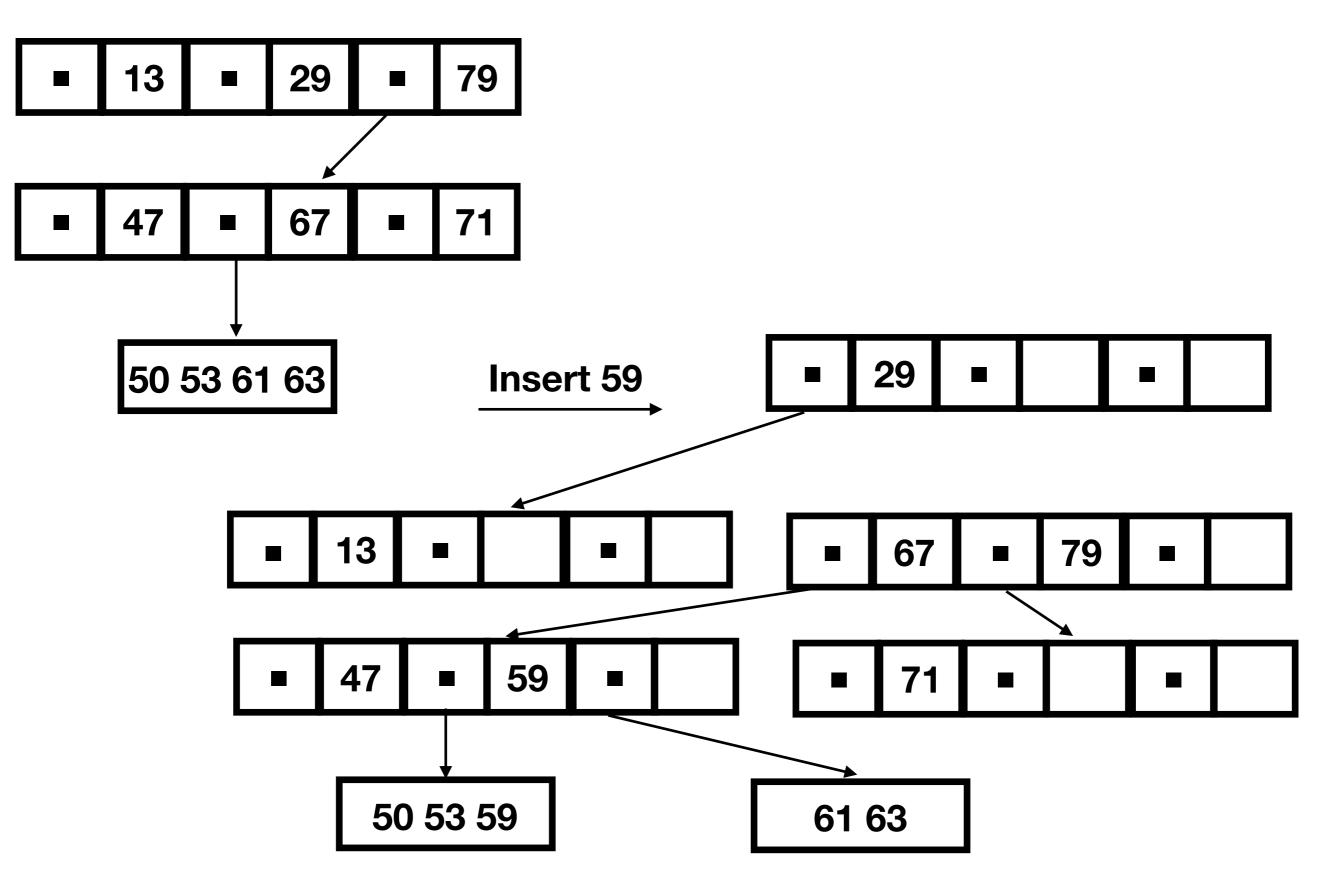

- Linear or binary search in each node given max. # of keys in node
- If not found, follow the appropriate child pointer
- Complexity: log_B(N)

B+-Trees - Insertion (3/3)

B+-Trees - Deletion

- An element is removed from the leaf
 - if leaf becomes empty, remove key from parent
 - Keep adjusting parent and its siblings to satisfy invariants
 - May ripple to root and reduce height of tree by 1
 - If the node has < 50% occupancy, merge it with left/right node (standard B+-Trees have a minimal occupancy of 50%)

B+-Trees - Complexity

Time Complexity

Search: O(B * log_B(n))

Insertion: O(B * log_B(n))

Deletion: O(B * log_B(n))

- Space Complexity
 - O(n)

B+-Trees - Advantages

- Multi-level Indexing
- Bulk Insertion
- Aggregation queries
- Value of B can be set to match the size of a disk sector or its multiples
